## 15-451 <br> $\mathfrak{A l g o r i t h m s}$

## Theory of $\mathfrak{N}(P$. Completeness

Randal E. Bryant<br>April 11, 2001

Topics:

- Turing Macfines
- Cook's Theorem
- Implications

## Turing Macfine

Formal Model of Computer

- Very primitive, but computationally complete

Tape

## Turing Macfine Components

Tape

- Conceptually infinite number of "squares" in botf directions
- Eack square holds one "symbol"
- From a finite alpfabet
- Initially holds input + copies of blank symbol ' $\mathcal{B}$ '

Tape $\mathcal{H e a d}$

- On each step
- Read current symbol
- Write ne w symbol
- Move Left or Right one position

## Components (Cont.)

Controller

- Has state between 0 and m-1
- Initial state $=0$
- Accepting state $=m-1$
- Performs steps
- Read symbol
- Write ne w symbol
- Move head left or right

Program

- Set of allowed controller actions
- Current State, Read Symbol $\rightarrow \mathcal{N} e w S$ Sate, $\mathcal{W}$ rite Symbol, $\mathcal{L} \mid \mathcal{R}$

## Turing Machine Program Example

Language Recognition

- Determine whether input is string of form $0^{n} 1^{n}$

Input Examples

- Should reach state m-1

- Should never reacf state m-1

## Algorithm

- Ke ep erasing 0 on left and 1 on rigft
- Terminate and accept when fave blank tape

## Program

States

- 0 Initial
- 1 Check Left
- 2 Scan Right
- 3 Check Right
- 4 Scan Left
- 5 Accept

-'means no possible action from this point
$\mathcal{D e}$ terministic $\mathcal{T M}: \mathcal{A}$ most one possible action at any point

## $\mathcal{N}$ on $\operatorname{Deterministic~} \mathcal{T} u r i n g ~ M a c \not \approx i n e ~$

Language Recognition

- Determine whether input is string of form $x x$
- For some string $\chi \in\{0,1\}^{*}$

Input Examples

- Should reach state m-1

- Should never reach state m-1

## $\mathcal{N}$ ondeterministic $\mathcal{A l g o r i t f m}$

- Record leftmost symbol and set to $\mathcal{B}$

- Scan right, stopping at arbitrary position with matcfing symbol, and mark it with 2

- Scan left to end, and run program to recognize $x 2^{+} \chi$

## $\mathcal{N}$ ondeterministic $\mathcal{A l g o r i t f m}$

- Migft make bad guess

- Program will never reach accepting state

Rule

- String accepted as long as reach accepting state for some sequence of steps

## $\mathcal{N}$ ondeterministic Program

States

- 0 Initial
- 1 Record
- 2 Look for 0
- 3 Look for 1
- 4 Scan Left
- 5+Rest of program

Read Symbol

$\mathcal{N}$ Nondeterministic $\mathcal{T M}: \geq 2$ possible actions from single point

## Turing Machine Complexity

Machine $\mathcal{M}$ Recognizes Input String $x$

- Initialize tape to x
- Consider all possible execution sequences
- Accept in time $t$ if can reach accepting state in $t$ steps $-t(\chi):$ Length of shortest accepting sequence for input $\chi$
Language of Mackine $\mathcal{L}(\mathcal{M})$
- Set of all strings that macfine accepts
- x $\notin \mathcal{L}$ when no execution sequence reaches accepting state
- Might fit de ad end
- Migft run forever

Time Complexity

- $\mathcal{T}_{\mathcal{M}}(n)=\operatorname{Max}\{t(x)|x \in \mathcal{L}| x \mid=n\}$
- Where $|x|$ is length of string $x$

## $P$ and $\mathcal{N} P$

Language $\mathcal{L}$ is in $P$

- There is some deterministic $\mathcal{T M} \mathcal{M}$
$-\mathcal{L}(\mathcal{M})=\mathcal{L}$
$-\mathcal{T}_{\mathcal{M}}(n)=p(n)$ for some polynomial function $p$
Language $\mathcal{L}$ is in $\mathcal{N}(P$
- There is some nondeterministic $\mathcal{T M} \mathcal{M}$
$-\mathcal{L}(\mathcal{M})=\mathcal{L}$
$-\mathcal{T}_{\mathcal{M}^{\prime}}(n)=p(n)$ for some polynomial function $p$
- Any problem that can be solved by intelligent guessing

## Example: Boole an Satisfiability

Problem

- Variables: $\quad x_{1}, \ldots, x_{k}$
- Literal: either $x_{i}$ or $\neg \chi_{i}$
- Clause: Set of literals
- Formula: Set of clauses
- Example: $\left\{x_{3}, \neg x_{3}\right\} \quad\left\{x_{1}, x_{2}\right\}\left\{\neg x_{2}, x_{3}\right\}\left\{x_{1}, \neg x_{3}\right\}$
- Denotes Boole an formula $x_{3} \vee \neg x_{3} \wedge x_{1} \vee x_{2} \wedge \neg x_{2} \vee x_{3} \wedge x_{1} \vee \neg x_{3}$

## Encoding Boole an Formula

Represent eacf clause as string of $2 \mathcal{K} 0$ 's and 1 's

- 1 bit for each possible literal
- First 6it: variable, Second 6it: Negation of variable
- $\left\{x_{3}, \neg x_{3}\right\}: 000011 \quad\left\{x_{1}, x_{2}\right\}: 101000$
- $\left\{\neg x_{2}, x_{3}\right\}: 000110 \quad\left\{x_{1}, \neg x_{3}\right\}: 100001$

Represent formula as clause strings separated by'\$'
-000011\$101000\$000110\$100001

## $\mathcal{S A T}$ is $\mathcal{N} P$

## Claim

- There is a $\mathfrak{N D} \mathcal{D} \mathscr{M} \mathfrak{M}$ such that $\mathcal{L}(\mathcal{M})=$ encodings of all satisfiable Boole an formulas

## $\mathfrak{A l g o r i t h m}$

- Pfase 1: Determine $K$ and generate some string $\{01,10\}$
- Append to end of formula
- This will be a guess at satisfying assignment
-E.g., $000011 \$ 101000 \$ 000110 \$ 100001 \$ 100110$
- Phase 2: Checkeach clause for matching 1
-E.g., $0000 \underline{11} \$ 101000 \$ 000110 \$ 100001 \$ 100110$

## $\mathcal{S A T}$ is $\mathfrak{N} \operatorname{P-complete}$

Cook's Theorem

- Cangenerate Boolean formula that checks whether $\mathcal{N D} \mathcal{D T M}$ accepts string in polynomial time
Translation Procedure
- Given
$-\mathcal{N D} \mathcal{D} \mathcal{M}$
- Polynomial function $p$
- Input string x

- Generate formula $\mathcal{F}$
$-\mathcal{F}$ is satisfiable iff $\mathcal{M}$ accepts $\chi$ in time $p(|\chi|)$
- Size of $\mathcal{F}$ is polynomial in $|x|$
- Procedure generates $\mathcal{F}$ in (deterministic) time polynomial in $|x|$

## Construction

Parameters

- $|x|=n$
- m states
- v tape symbols (including $\mathcal{B})$

Formula Variables

- $Q[i, k] \quad O=i=p(n), O=K=m-1$
- $\mathfrak{A}$ t time $i, \mathcal{M}$ is in state $K$
- $\mathcal{H}[i, j]$

$$
0=i=p(n),-p(n)=j=p(n)
$$

$-\mathcal{A}$ time $i$, tape head is over square $j$

- $\mathcal{S}[i, j, k] \quad 0=i=p(n),-p(n)=j=p(n), 1=k=v$
- At time $i$, tape square $j$ folds symbolk

Key Observation

- For bounded computation, can only visit bounded number of squares

## Clause Groups

- Formula clauses divided into "clause groups"

## Uniqueness

- At each time i, $\mathcal{M}$ is in exactly one state
- At eacf time i, tape fead over exactly one square
- At each time i, each square j contains exactly one symbol

## Initialization

- At time 0, tape encodes input $x$, head in position 0 , controller in state 0

## Accepting

- At some time $i$, state $=m-1$

Legal Computation

- Tape/Head/Controller configuration at each time $i+1$ follows from that at time $i$ according to some legal action

## Implications of Cook's Theorem

Suppose There Were an Efficient $\mathcal{A l g o r i t h}$ for Boole an Satisfiability

- Then could take any problem in $\mathcal{N}(P$, convert it to $\mathcal{B o o l e}$ an formula and solve it quickly!
- Many "fiard" problems would suddenly be easy
$\mathcal{B i g}$ Question $\mathcal{P}=$ ? $\mathcal{N}(P$
- Formulated in 1971
- Still not solved
- Most believe not

## Complements of Problems

Language Complement

- Define $\sim \mathcal{L}=\{x \mid x \notin \mathcal{L}\}$
- E.g., $\sim \mathcal{S} \mathcal{A} \mathcal{T}$
- Malformed formulas (easy to detect)
- Unsatisfiable formulas

PClosed Under Complementation

- If $\mathcal{L}$ is in $\mathcal{P}$, then so is $\sim \mathcal{L}$
- Run $\mathcal{T M}$ for $\mathcal{L}$ on input $\chi$ for $p(|\chi|)$ steps
» Has unique computation sequence
- If haven't reached accepting state by then, then $\chi \notin \mathcal{L}$

## $\mathcal{N} \mathbb{P}$ vs. co- $\mathcal{N} P(c o n t$.

Is $\mathcal{N}(P=\operatorname{co}-\mathcal{N}(P$ ?

- Having $\mathfrak{N D T M}$ for $\sim \mathcal{L}$ doesn't felp for recognizing $\mathcal{L}$
- Would have to checkall computation sequences of length $=p(|x|)$.
- Could fiave exponentially many sequences

Proper Terminology

- Generally want algorithm that can terminate with "yes"or "no" answer to decision problem
- If underlying problem (or its complement) is $\mathcal{N}(P$, then full decision problem is " $\mathcal{N}$ P- Hard"

## Sfowing Problems $\mathcal{N}$ P-Complete

To show Problem $X$ is $\mathcal{N}(P$-complete

1. Show $X$ is in $\mathcal{N} P$

- Can be solved by "guess and check"
- Generally easy part

2. Show known $\mathcal{N}$ (P-complete problem $\mathcal{Y}$ can be reduced to $X$

- Devise translation procedure
- Given arbitrary instance $y$ of $Y$, can generate problem $x$ in $X$ such that $y \in L_{y}$ iff $x \in \mathcal{L}_{x}$
- $\mathcal{L}_{\chi}$ : set of all strings $\chi$ for which decision problem answer is "yes"
- Size of $x$ must be polynomial in $y$, and must be generated by (deterministic) polynomial algorithm.
