

Is the WWW a DBMS?
 Fairly sophisticated search available

 crawler *indexes* pages for fast search
 But, currently
 data is mostly unstructured and untyped
 can't manipulate the data
 few guarantees provided for freshness of data, consistency across data items, fault tolerance, ...
 Web sites typically have a DBMS in the background to provide these functions.

 The picture is quickly changing

 New standards like XML can help data modeling
 Research groups are working on providing some of this functionality *across multiple web sites*.

Yet traditional focus on real-world apps

About the course - Workload

- · Projects this semester cover:
 - DBMS Internals
 - (requires systems programming in "C")
 - Database Query design, optimization and processing
 - Database Applications
- · Other homework assignments and/or quizes
- Exams 1 Midterm & 1 Final
- · Projects to be done in groups of 3

YOU WILL NOT RECEIVE A GOOD GRADE IN THE COURSE IF YOUR EXAM SCORES ARE POOR (Regardless of project grades)

About the Course - Administrivia

- http://www.cs.cmu.edu/~natassa/15-415
- Prof. Office Hours:
- Wean Hall 7109, Mondays 3-4pm (except today)
- TAs: Spiros Papadimitriou, Minglong Shao, Joey Trdinich
 - Office Hours: (check web page)

- mail broadcast to all TAs will not be answered
- Announcements: academic.cs.15-415.announce
 Only Prof. Posts course announcements in this newsgroup

A 15-415 Infomercial

- A "free tasting" of things to come in this class:
 - data modeling
 - Query languages
 - file systems & DBMSs
 - concurrent, fault-tolerant data management
 - DBMS architecture
- Next Time
 - Database Design using the Entity-Relationship model
- · Today's lecture is from Chapter 1 in R&G
- Read Chapter 2 for next class.

OS Support for Data Management

· Data can be stored in RAM

- this is what every programming language offers!
- RAM is fast, and random access
- Isn't this heaven?

Every OS includes a File System

- manages *files* on a magnetic disk
- allows open, read, seek, close on a file
- allows protections to be set on a file
- drawbacks relative to RAM?

D

Database Management Systems

- · What more could we want than a file system?
 - Simple, efficient ad hoc1 queries
 - concurrency control
 - recovery
 - benefits of good data modeling
- S.M.O.P.²? Not really...
 - as we'll see this semester
 - in fact, the OS often gets in the way!

¹ad hoc: formed or used for specific or immediate problems or needs ²SMOP: Small Matter Of Programming

Describing Data: Data Models

- A <u>data model</u> is a collection of concepts for describing data.
- A <u>schema</u> is a description of a particular collection of data, using a given data model.
- The *relational model of data* is the most widely used model today.
 - Main concept: <u>relation</u>, basically a table with rows and columns.
 - Every relation has a <u>schema</u>, which describes the columns, or fields.

Levels of Abstraction Users · Views describe how users see the data. · Conceptual schema View 1 View 2 View 3 defines logical structure Conceptual Schema Physical schema Physical Schema describes the files and indexes used. DB (sometimes called the ANSI/SPARC model)

Example: University Database

Conceptual schema:

- Students(sid: string, name: string, login: string, age: integer, gpa:real)
- Courses(cid: string, cname:string, credits:integer)
- Enrolled(sid:string, cid:string, grade:string)

Physical schema:

- Relations stored as unordered files.
- Index on first column of Students.
- External Schema (View):
 - Course_info(cid:string,enrollment:integer)

Data Independence

- Applications insulated from how data is structured and stored.
- Logical data independence: Protection from changes in *logical* structure of data.
- <u>Physical data independence</u>: Protection from changes in *physical* structure of data.
- Q: Why is this particularly important for DBMS?

Because databases and their associated applications persist.

Concurrency Control

- Concurrent execution of user programs: key to good DBMS performance.
 - Disk accesses frequent, pretty slow
 - Keep the CPU working on several programs concurrently.
- Interleaving actions of different programs: trouble!
 - e.g., deposit & withdrawal on same account
- DBMS ensures such problems don't arise: users can pretend they are using a singleuser system. (called "Isolation")
 - Thank goodness!

Transaction: An Execution of a DB Program

- Key concept is a transaction: an atomic sequence of database actions (reads/writes).
- Each transaction, executed completely, must take the DB between consistent states.
- Users can specify simple integrity constraints on the data. The DBMS enforces these.
 - Beyond this, the DBMS does not understand the semantics of the data.
 - Ensuring that a single transaction (run alone) preserves consistency is ultimately the user's responsibility!

Scheduling Concurrent Transactions

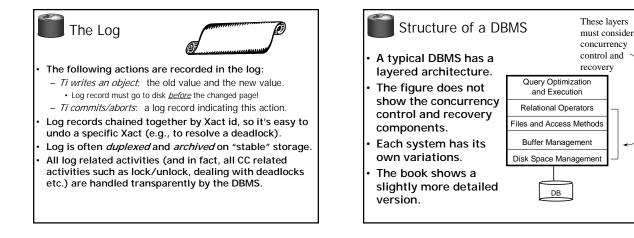

DBMS ensures that execution of {T1, ..., Tn} is equivalent to some *serial* execution T1' ... Tn'.

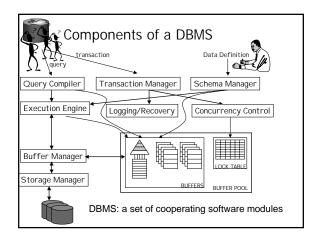

- Before reading/writing an object, a transaction requests a lock on the object, and waits till the DBMS gives it the lock. All locks are held until the end of the transaction. (<u>Strict 2PL</u> locking protocol.)
- Idea: If an action of Ti (say, writing X) affects Tj (which perhaps reads X), one of them, say Ti, will obtain the lock on X first and Tj is forced to wait until Ti completes; this effectively orders the transactions.
- What if Tj already has a lock on Y and Ti later requests a lock on Y? (<u>Deadlock</u>!) Ti or Tj is <u>aborted</u> and restarted!

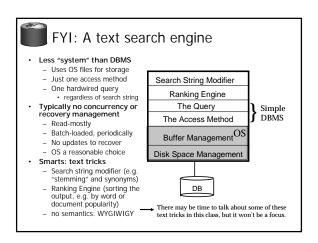

Ensuring Transaction Properites

DBMS ensures *atomicity* (all-or-nothing property) even if system crashes in the middle of a Xact.

- DBMS ensures *durability* of *committed* Xacts even if system crashes.
- Idea: Keep a <u>log</u> (history) of all actions carried out by the DBMS while executing a set of Xacts:
 - Before a change is made to the database, the corresponding log entry is forced to a safe location.
 (<u>WAL protocol</u>: OS support for this is often inadequate.)
 - After a crash, the effects of partially executed transactions are <u>undone</u> using the log. Effects of committed transactions are <u>redone</u> using the log.
 - trickier than it sounds!

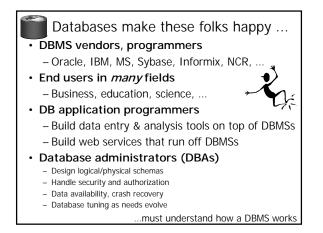

Advantages of a DBMS

- · Data independence
- Efficient data access
- · Data integrity & security
- · Data administration
- · Concurrent access, crash recovery
- · Reduced application development time
- · So why not use them always?
 - Expensive/complicated to set up & maintain
 - This cost & complexity must be offset by need
 - General-purpose, not suited for special-purpose tasks (e.g. text search!)

Summary (part 1)

- DBMS used to maintain, query large datasets.
 can manipulate data and exploit *semantics*
- Other benefits include:
 - recovery from system crashes,
 - concurrent access,
 - quick application development,
 - data integrity and security.
- Levels of abstraction provide data independence.
- In this course we will explore:
 - 1) How to be a sophisticated user of DBMS technology
 - 2) What goes on inside the DBMS
